ABSTRACT

We critically evaluate the role of radiation and ram pressure in providing internal support for the bow-shaped infrared arc around the massive triple star system σ Ori Aa/Ab/B in the IC434 H II region. We present evidence for hydrogen recombination line emission from the arc, which demonstrates that it cannot be a decoupled dust wave, as has previously been claimed. On the other hand, we show that the fraction of the stellar luminosity trapped by the arc is insufficient for it to be supported by radiation if the grains and gas are well coupled. Therefore, the arc must be supported by the ram pressure of an internal wind. However, the stellar winds from the OB stars in the σ Ori Aa/Ab/B system seem too weak to provide this support on their own. We propose instead that it is the photoevaporated disk wind from the enclosed proplyd IRS 1B that dominates the ram pressure support for the bow.

Key words: circumstellar matter – radiation: dynamics – stars: winds, outflows

1 WHY THE INNER ARC CANNOT BE A DECOUPLED DUST WAVE

We downloaded optical images of σ Ori from the Astronomical Data Centre of the Cambridge Astronomy Survey Unit.¹ These were obtained on 2008-11-19 with the Wide Field Camera of the Isaac Newton Telescope from an observational program of Rafael Barrena. We use images in two filters: a narrow-band H α filter (central wavelength, $\lambda_0 = 656.8$ nm, full-width half maximum, $\Delta\lambda = 9.5$ nm) and a broad-band Sloan Gunn R filter ($\lambda_0 = 624.0$ nm, $\Delta\lambda = 134.7$ nm). We have removed the bias v
